Our data suggest that percutaneous closure of baffles is a safe procedure and the medium-term follow-up demonstrates no recurrences of the leaks and good clinical status.

Delayed Positive Response to a Flecainide Test in a Patient With Suspected Brugada Syndrome: a Worrisome Finding

Respuesta positiva diferida al test de flecainida en paciente con sospecha de síndrome de Brugada: un hallazgo preocupante

To the Editor,

Drug challenge tests used to elicit a Brugada electrocardiographic pattern (B-ECG) are fundamental in the diagnosis of this syndrome. Sodium channel blockers used in the treatment of cardiac arrhythmias, mainly ajmaline and flecainide, are the agents most widely employed because of their demonstrated efficacy and safety in unmasking the B-ECG. The results of the test are considered positive if, during infusion of the drug, a nondiagnostic B-ECG (type 2 or 3) becomes a diagnostic B-ECG (type 1 or coved type), which is characterized by ST segment elevation ≥ 2 mm followed by a negative T wave in more than 1 precordial lead (V1-V3). These tests are usually performed in an outpatient setting and, once the electrocardiogram has become normalized, the patient is discharged after a short monitoring period. There is no information in the literature concerning the incidence and implications of late positive responses following an initially negative flecainide test (FT).

We report the case of a 32-year-old man who was asymptomatic and had no family history of sudden cardiac death. He was referred to our hospital to undergo a FT when he was found to have a type 3 B-ECG in a routine electrocardiogram. The results of a physical examination and a battery of analyses were normal. The existence of structural heart disease was ruled out by echocardiography. A baseline electrocardiogram performed prior to the FT revealed no abnormalities. Following flecainide infusion (2 mg/kg body weight for 10 minutes), the patient had a significantly prolonged QRS interval, but met none of the diagnostic criteria for B-ECG (with precordial leads V1 and V2 placed both in the fourth and in the third intercostal space). Although the widening of the QRS complex did not meet the criteria for interrupting the test (QRS > 130% of baseline value), he was admitted to the hospital for electrocardiographic monitoring until the intraventricular conduction disturbance had been corrected. Two hours after completing the administration of flecainide, we detected coved ST-segment elevation in the right precordial leads, a finding that met the criteria for type 1 B-ECG (Figure). Twenty-four hours later, the electrocardiogram had returned to normal and the patient was discharged home.

This report describes a case of a late positive response to FT after an initial negative result. It was discovered incidentally because the patient underwent a longer than usual period of electrocardiographic monitoring.

Among the antiarrhythmic sodium channel blockers currently available, ajmaline has been found to exhibit the greatest efficacy in unmasking B-ECG. Hong et al1 evaluated ajmaline in a cohort of 147 carriers of mutations in the SCN5A gene. They reported a diagnostic sensitivity and specificity of 80% and 94%, respectively, as well as a positive predictive value of 93% and negative predictive value of 83% for he syndrome. Meregalli et al2 analyzed the effect of flecainide in 110 carriers of the same gene; they obtained a sensitivity of 77%, specificity of 80%, positive predictive value of 96%, and negative predictive value of 36%. The 2 drugs were compared in a study by Wolpert et al3 involving 22 probands with a genetic diagnosis of Brugada syndrome; ajmaline had a higher detection capacity (22 of 22) than flecainide (15 of 22) and a more marked ST-segment elevation. The reproducibility of FT has also been controversial. Gasparini et al4 found a reproducibility of 100%. However, there are reports of cases in which the test was negative, although the initial response had been positive.5

Despite the superiority of ajmaline, the fact that in many countries it is not available has made flecainide the drug of choice in most electrophysiology laboratories. The differences between the 2 drugs have been related to flecainide’s greater inhibition of the transient outward potassium current (I中毒). This reduces the ionic imbalance between the positive inward and outward
currents at the end of phase 1 of the action potential that enables the unmasking of the B-ECG.

The case of a delayed positive response to flecainide reported here might indicate that results considered to be negative at the time of the challenge test may be false negatives, since the electrocardiographic monitoring time is usually 30 minutes or less.

Studies involving a larger number of patients should be carried out to examine whether the systematic prolongation of the monitoring period following a FT could contribute to reducing the number of false negatives.

Infranodal Atioventricular Block as a Possible Cause of Exercise-induced Cardiac Arrest

Bloqueo auriculoventricular infranodular como posible causa de parada cardiaca inducida por ejercicio

To the Editor,

Cardiac arrest that occurs during long-distance running races is most commonly attributed to hypertrophic cardiomyopathy or atherosclerotic coronary disease. Conduction system disease is an extremely rare cause of sudden death in athletes and the final cause remains unknown in a small proportion of cases.1 We present a case of malignant bradyarrhythmia in a long distance runner.

A 46-year-old healthy man, with no previous cardiovascular history, had a cardiac arrest immediately after completing a half marathon. At the finish line, he fainted and was attended by the emergency medical services, which initiated advanced life support in the presence of severe bradycardia (23 bpm) and hypotension. A first electrocardiogram showed complete atioventricular block (AVB) with slow wide QRS complex escape (Figure 1A). Intravenous atropine only increased sinus rate without improving the degree of AVB (Figure 1B) and therefore a transcutaneous
